

Name: Bueno, Joshua C.	Date Performed: 09/12/2025
Course/Section: CPE212 / CPE31S2	Date Submitted: 09/19/2025
Instructor: Engr. Robin Valenzuela	Semester and SY: 1st semester / 2025-2026

Activity 5: Consolidating Playbook plays

1. Objectives:

- 1.1 Use **when** command in playbook for different OS distributions
- 1.2 Apply refactoring techniques in cleaning up the playbook codes

2. Discussion:

We are going to look at a way that we can differentiate a playbook by a host in terms of which distribution the host is running. It's very common in most Linux shops to run multiple distributions, for example, Ubuntu shop or Debian shop and you need a different distribution for a one off-case or perhaps you want to run plays only on certain distributions.

It is a best practice in ansible when you are working in a collaborative environment to use the command `git pull`. `git pull` is a Git command used to update the local version of a repository from a remote. By default, `git pull` does two things. Updates the current local working branch (currently checked out branch) and updates the remote-tracking branches for all other branches. `git pull` essentially pulls down any changes that may have happened since the last time you worked on the repository.

Requirement:

In this activity, you will need to create a CentOS VM. Likewise, you need to activate the second adapter to a host-only adapter after the installations. Take note of the IP address of the CentOS VM. Make sure to use the command **`ssh-copy-id`** to copy the public key to CentOS. Verify if you can successfully SSH to CentOS VM.

```
root@jgvmware-OptiPlex-5090:~# ssh-copy-id justinlim@192.168.56.114
/usr/bin/ssh-copy-id: INFO: attempting to log in with the new key(s), to filter out any that are already installed
/usr/bin/ssh-copy-id: INFO: 2 key(s) remain to be installed -- if you are prompted now it is to install the new keys
justinlim@192.168.56.114's password:

Number of key(s) added: 2
```

Task 1: Use when command for different distributions

- In the local machine, make sure you are in the local repository directory (**CPE232_yourname**). Issue the command git pull. When prompted, enter the correct passphrase or password. Describe what happened when you issue this command. Did something happen? Why?
 - When the command git pull was issued inside the local repository, Git attempted to fetch and merge updates from the remote repository into the local copy**
- Edit the inventory file and add the IP address of the Centos VM. Issue the command we used to execute the playbook (the one we used in the last activity): **ansible-playbook --ask-become-pass install_apache.yml**. After executing this command, you may notice that it did not become successful in the Centos VM. You can see that the Centos VM has failed=1. Only the two remote servers have been changed. The reason is that Centos VM does not support "apt" as the package manager. The default package manager for Centos is "yum."
 - Edit the **install_apache.yml** file and insert the lines shown below.

```
---
- hosts: all
  become: true
  tasks:

    - name: update repository index
      apt:
        update_cache: yes
      when: ansible_distribution == "Ubuntu"

    - name: install apache2 package
      apt:
        name: apache2
      when: ansible_distribution == "Ubuntu"

    - name: add PHP support for apache
      apt:
        name: libapache2-mod-php
      when: ansible_distribution == "Ubuntu"
```

Make sure to save the file and exit.

Run **ansible-playbook --ask-become-pass install_apache.yml** and describe the result.

```
TASK [update repository index] ****
changed: [192.168.56.110]
changed: [192.168.56.111]
changed: [192.168.56.112]

192.168.56.110      : ok=4    changed=1    unreachable=0    failed=0    skipped=0
192.168.56.111      : ok=4    changed=1    unreachable=0    failed=0    skipped=0
192.168.56.112      : ok=4    changed=1    unreachable=0    failed=0    skipped=0
192.168.56.114      : ok=0    changed=0    unreachable=0    failed=1    skipped=0
```

-The ip address of centOS failed because it dont support apt.

If you have a mix of Debian and Ubuntu servers, you can change the configuration of your playbook like this.

- name: update repository index
 apt:
 update_cache: yes
 when: ansible_distribution in ["Debian", "Ubuntu"]

Note: This will work also if you try. Notice the changes are highlighted.

4. Edit the *install_apache.yml* file and insert the lines shown below.

```
---
- hosts: all
  become: true
  tasks:

    - name: update repository index
      apt:
        update_cache: yes
      when: ansible_distribution == "Ubuntu"

    - name: install apache2 package
      apt:
        name: apache2
        state: latest
      when: ansible_distribution == "Ubuntu"

    - name: add PHP support for apache
      apt:
        name: libapache2-mod-php
        state: latest
      when: ansible_distribution == "Ubuntu"

    - name: update repository index
      dnf:
        update_cache: yes
      when: ansible_distribution == "CentOS"

    - name: install apache2 package
      dnf:
        name: httpd
        state: latest
      when: ansible_distribution == "CentOS"

    - name: add PHP support for apache
      dnf:
        name: php
        state: latest
      when: ansible_distribution == "CentOS"
```

Make sure to save and exit.

Run *ansible-playbook --ask-become-pass install_apache.yml* and describe the result.

This is for my ubuntu two control nodes

```

- To verify the installations, go to CentOS VM and type its IP address on the browser. Was it successful? The answer is no. It's because the httpd service or the Apache HTTP server in the CentOS is not yet active. Thus, you need to activate it first.

The screenshot shows a Firefox browser window with the URL `https://192.168.56.114` in the address bar. The page content is titled "Unable to connect" and contains the following text:
An error occurred during a connection to 192.168.56.114.

- The site could be temporarily unavailable or too busy. Try again in a few moments.
- If you are unable to load any pages, check your computer's network connection.
- If your computer or network is protected by a firewall or proxy, make sure that Firefox is permitted to access the web.

A blue "Try Again" button is visible at the bottom right of the error message area.

5.1 To activate, go to the CentOS VM terminal and enter the following:
systemctl status httpd

```
@vbox ~]$ systemctl status httpd
● httpd - The Apache HTTP Server
   loaded (/usr/lib/systemd/system/httpd.service; disabled; preset: disabled)
   n: /usr/lib/systemd/system/httpd.service.d
      └─php-fpm.conf
   e: inactive (dead)
   s: man:httpd.service(8)
6 (END)
```

It is disabled

The result of this command tells you that the service is inactive.

5.2 Issue the following command to start the service:
sudo systemctl start httpd

```
m@vbox ~]$ sudo systemctl start httpd
start: httpd.service: Unit httpd.service not found.
```

```
m@vbox ~]$
```

The screenshot shows a web browser window with the URL `192.168.56.104` in the address bar. The page title is "HTTP Server Test Page". The content includes a message for the general public, instructions for website administrators, and notes for systems using the Apache HTTP Server. At the bottom, there are two terminal command examples:

```
@vbox ~]$ sudo systemctl start httpd  
@vbox ~]$ sudo firewall-cmd --add-port=80/tcp
```

Below the terminal examples, a task is listed:

5.3 To verify the service is already running, go to CentOS VM and type its IP address on the browser. Was it successful? (Screenshot the browser)

The screenshot shows a Firefox browser window with the title bar "Activities" and "Firefox" and the date "Sep 19 17:09". The address bar shows "HTTP Server Test Page" and "192.168.56.114". Below the address bar, there are links for "CentOS", "Blog", "Documentation", and "Forums". The main content area has a dark background with a green and purple nebula-like pattern. The "CentOS" logo is in the top left. The title "HTTP Server Test Page" is centered. Below it, a message states: "This page is used to test the proper operation of the HTTP server after it has been installed. If you can read this page it means that this site is working properly. This server is powered by CentOS." Two callout boxes provide additional information:

- If you are a member of the general public:** The website you just visited is either experiencing problems or is undergoing routine maintenance.
- If you are the website administrator:** You may now add content to the webroot directory. Note that until you do so, people visiting your website will see this page, and not your content.

For systems using the Apache HTTP Server: You may now add content to the directory `/var/www/html/`. Note that until you do so, people visiting your website will see this page, and not your content. To prevent this page from

- It was a success

Task 2: Refactoring playbook

This time, we want to make sure that our playbook is efficient and that the codes are easier to read. This will also makes run ansible more quickly if it has to execute fewer tasks to do the same thing.

1. Edit the playbook `install_apache.yml`. Currently, we have three tasks targeting our Ubuntu machines and 3 tasks targeting our CentOS machine. Right now, we try to consolidate some tasks that are typically the same. For example, we can consolidate two plays that install packages. We can do that by creating a list of installation packages as shown below:

```
---
- hosts: all
  become: true
  tasks:

    - name: update repository index Ubuntu
      apt:
        update_cache: yes
      when: ansible_distribution == "Ubuntu"

    - name: install apache2 and php packages for Ubuntu
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
      when: ansible_distribution == "Ubuntu"

    - name: update repository index for CentOS
      dnf:
        update_cache: yes
      when: ansible_distribution == "CentOS"

    - name: install apache and php packages for CentOS
      dnf:
        name:
          - httpd
          - php
        state: latest
      when: ansible_distribution == "CentOS"
```

Make sure to save the file and exit.

```
--  
- hosts: all  
  become: true  
  tasks:  
  
  - name: update repository index Ubuntu  
    apt:  
      update_cache: yes  
    when: ansible_distribution == "Ubuntu"  
  
  - name: install apache2 and php packages for Ubuntu  
    apt:  
      name:  
        - apache2  
        - libapache2-mod-php  
      state: latest  
    when: ansible_distribution == "Ubuntu"  
  
  - name: update repository index for CentOS  
    dnf:  
      update_cache: yes  
    when: ansible_distribution == "CentOS"  
  
  - name: install apache and php packages for CentOS  
    dnf:  
      name:  
        - httpd  
        - php
```

```
- name: install apache and php packages for CentOS  
dnf:  
  name:  
    - httpd  
    - php  
  state: latest  
when: ansible_distribution == "CentOS"
```

Run *ansible-playbook --ask-become-pass install_apache.yml* and describe the result.

```

- I successfully installed another packages for my **CentOS** and **Ubuntu**
2. Edit the playbook *install_apache.yml* again. In task 2.1, we consolidated the plays into one play. This time we can actually consolidated everything in just 2 plays. This can be done by removing the update repository play and putting the command *update_cache: yes* below the command *state: latest*. See below for reference:

```

---
- hosts: all
  become: true
  tasks:

    - name: install apache2 and php packages for Ubuntu
      apt:
        name:
          - apache2
          - libapache2-mod-php
        state: latest
        update_cache: yes
        when: ansible_distribution == "Ubuntu"

    - name: install apache and php packages for Centos
      dnf:
        name:
          - httpd
          - php
        state: latest
        update_cache: yes
        when: ansible_distribution == "CentOS"

```

Make sure to save the file and exit.

```
- name: install apache2 and php packages for Ubuntu
  apt:
    name:
      - apache2
      - libapache2-mod-php
    state: latest
    update_cache: yes
  when: ansible_distribution == "Ubuntu"

- name: update repository index for CentOS
  dnf:
    update_cache: yes
  when: ansible_distribution == "CentOS"

- name: install apache and php packages for CentOS
  dnf:
    name:
      - httpd
      - php
    state: latest
    update_cache: yes
  when: ansible_distribution == "CentOS"
```

Run *ansible-playbook --ask-become-pass install_apache.yml* and describe the result.

```

- It proceeded to install and configure Apache on the target machine, showing the status of each task, but it failed

3. Finally, we can consolidate these 2 plays in just 1 play. This can be done by declaring variables that will represent the packages that we want to install. Basically, the apache_package and php_package are variables. The names are arbitrary, which means we can choose different names. We also take out

the line when: ansible_distribution. Edit the playbook *install_apache.yml* again and make sure to follow the below image. Make sure to save the file and exit.

```
---  
- hosts: all  
  become: true  
  tasks:  
  
  - name: install apache and php  
    apt:  
      name:  
        - "{{ apache_package }}"  
        - "{{ php_package }}"  
      state: latest  
      update_cache: yes
```

Run `ansible-playbook --ask-become-pass install_apache.yml` and describe the result.

```

TASK [Gathering Facts] *****

```

-The installation failed.

- Unfortunately, task 2.3 was not successful. It's because we need to change something in the inventory file so that the variables we declared will be in place. Edit the `inventory` file and follow the below configuration:

```
192.168.56.120 apache_package=apache2 php_package=libapache2-mod-php  
192.168.56.121 apache_package=apache2 php_package=libapache2-mod-php  
192.168.56.122 apache_package=httpd php_package/php
```

```
GNU nano 7.2                                         inventory.yaml  
[dbserver]  
192.168.56.111  
[workstation]  
192.168.56.112 apache_package=apache2 php_package=libapache2-mod-php  
192.168.56.110 apache_package=apache2 php_package=libapache2-mod-php  
192.168.56.114 apache_package=httpd php_package/php  
[webserver]  
192.168.56.112 apache_package=apache2 php_package=libapache2-mod-php  
192.168.56.110 apache_package=apache2 php_package=libapache2-mod-php  
192.168.56.114 apache_package=httpd php_package/php  
[CentOS]  
192.168.56.114 ansible_user=justinlim ansible_ssh_private_key_file=~/ssh/id_rsa
```

Make sure to save the `inventory` file and exit.

Finally, we still have one more thing to change in our `install_apache.yml` file. In task 2.3, you may notice that the package is assign as `apt`, which will not run in CentOS. Replace the `apt` with `package`. Package is a module in ansible that is generic, which is going to use whatever package manager the underlying host or the target server uses. For Ubuntu it will automatically use `apt`, and for CentOS it will automatically use `dnf`. Make sure to save the file and exit. For more details about the ansible package, you may refer to this documentation: [ansible.builtin.package — Generic OS package manager — Ansible Documentation](#)

```
---  
- hosts: all  
  become: true  
  tasks:  
    - name: install apache and php  
      package:  
        name:  
          - "{{ apache_package }}"  
          - "{{ php_package }}"  
        state: latest  
        update_cache: yes
```

Run `ansible-playbook --ask-become-pass install_apache.yml` and describe the result.

```

```
ding line appears to be:\n\n...+ name: install apache and php\n      " here\n]\nok: [192.168.56.112]\nok: [192.168.56.118]\n\nTASK [update repository index Ubuntu] *****\nchanged: [192.168.56.110]\nchanged: [192.168.56.112]\n\nTASK [install apache2 and php packages for Ubuntu] *****\nok: [192.168.56.112]\nok: [192.168.56.118]\n\nTASK [update repository index for CentOS] *****\nskipping: [192.168.56.112]\nskipping: [192.168.56.110]\n\nTASK [install apache and php packages for CentOS] *****\nskipping: [192.168.56.112]\nskipping: [192.168.56.110]\n\nPLAY RECAP *****\n192.168.56.110      : ok=4    changed=1    unreachable=0    failed=0    skipped=2\n192.168.56.111      : ok=1    changed=0    unreachable=0    failed=1    skipped=0\n192.168.56.112      : ok=4    changed=1    unreachable=0    failed=0    skipped=2\n192.168.56.114      : ok=0    changed=0    unreachable=0    failed=1    skipped=0
```

After I change my inventory.yml the installation was successful.

Supplementary Activity:

1. Create a playbook that could do the previous tasks in Red Hat OS.

```
GNU nano 5.6.1                               install_apache.yml                         Modified
---
- hosts: all
- become: true
tasks:
- name: installing Apache2 and PHP Packages
- package:
  name:
    - httpd
    - php

state: latest
update_cache: yes
when ansible_distribution == "RedHat"
```

Reflections:

Answer the following:

1. Why do you think refactoring of playbook codes is important? It makes sure that our code is running.
 - Refactoring playbook codes is important because it keeps the code clean and organized. It makes the playbook easier to maintain and update in the future. It also reduces redundancy, improves readability, and ensures that the code runs smoothly.
2. When do we use the “when” command in playbook? executes a single task
 - The “when” command is used to execute a task only if a specific condition is met. It allows playbooks to be more flexible by adapting tasks to different scenarios. This helps prevent unnecessary executions and makes automation more efficient.
